Screenshot of a working app:

Use of AI Tools During the Assessment

For this assessment, we worked as a group of three and used AI tools to support us while building the HealthEase application. We did not use AI to do the whole project for us - we used it to help us understand things better, come up with ideas, fix errors in our code, and improve the overall design.

We mostly used AI during development and when debugging. Whenever we had a bug or could not figure out why a certain part of our code was not working, we asked AI for help to understand what could be causing the problem and how to fix it. We then went through the suggestions ourselves, tested them, and changed the code to fit what our app needed.

AI also helped us learn. When we came across programming concepts or processes that we did not fully understand, we asked AI to explain them in a simpler way and give us examples of how we could implement certain features. We used these explanations to learn from, but we did the final coding and testing on our own.

For the UI/UX design, we used AI to get ideas for different screens, how the navigation should work, and possible layouts for Health Ease. The ideas from AI were just used as a guide, and our group made all the final decisions about the design, features, and how the user moves through the app.

We also used AI to help check our work for errors. If AI gave us code suggestions or examples, we did not just copy and paste them. We reviewed them first, made sure we understood them, and edited them to make sure they were suitable for our project.

Overall, all three members of the group were involved in developing, making decisions, testing, and completing the project. AI was only used as an extra tool to help us learn, brainstorm, fix problems, and improve our work, not to replace our own effort. Where we used AI assistance, we acknowledged it as required by the assessment guidelines.
